Brucellosis has a wide spectrum of clinical manifestations which may last from several days to more than a year. It is often misdiagnosed, which results in inadequate therapy and prolonged illness as brucellosis requires protracted combined antimicrobial treatment. Although brucellosis rarely is fatal, it can be severely debilitating and disabling. The 10 recognized *Brucella* species have variable host preferences but most also are pathogenic for humans. Virulence mostly resides in its ability to enter, survive and replicate within host cells. Complete genome analyses have not identified classic virulence factors. Brucellosis occurs worldwide and its prevalence remains very high among ruminant livestock in many developing countries, where prevalence rates in humans that exceed 10 cases per 100,000 population are documented despite its being commonly undiagnosed and under-reported. The leading source of human infections is consumption of infectious raw milk and dairy products made from raw milk. Control of brucellosis in humans requires the pasteurization of milk and eradication from livestock.
